

Saltmere Coastal Observatory

The Saltmere Coastal Observatory is a fictional monitoring outpost perched on the cliffs of the Verdigris Strait. Commissioned by the Thalassic Institute in 2017, it tracks fog banks, wind shear, and salinity plumes for the ferry corridor below.

Its laser ceilometer, nicknamed Firefly, measures cloud-base height up to 12,400 meters and fires 5,500 pulses per second.

Instrument schedule

Instrument	Serial	Calibration interval
Ceilometer "Firefly"	SC-201	90 days
Anemometer array	SC-114	30 days
Salinity probe	SC-377	45 days

Data archive

During each winter season the observatory archives 7.3 terabytes of lidar returns to vaults on the mainland. The archive is mirrored to the Thalassic Institute every 14 days by microwave link, and a sealed tape copy travels out with the quarterly supply boat.
